Summary

*Tephrosia Falciformis* Linn. (Fabaceae) is is a rigid perennial much branched shrub, found as weed throughout India. The ethanolic extract of the roots of *Tephrosia Falciformis* (EETF) at 100, 200 and 400mg/kg/p.o was screened in rats for anti-inflammatory activity by acute-carrageenan induced paw edema, sub-acute cotton pellet induced granuloma and chronic Freund’s adjuvant induced arthritis models. In all the three models of anti-inflammatory studies 200 and 400mg/kg/p.o doses of the extract showed significant effect (P<0.001). Antinociceptive evaluation was performed by writhing and tail-immersion tests in mice. anti-nociceptive evaluation revealed that EETF at the dose of 400mg/kg/p.o had significant activity against the control. The relieving effect was through the peripheral and central mechanism of action of the extract. This study rationalized the ethno medicinal use of the plant for relieving pain in inflammatory pathological conditions like fracture and dislocation.

Key Words: *Tephrosia Falciformis*, Carrageenan, Cotton pellet, Freund’s adjuvant, Writhing test, Tail immersion test.
Introduction

Inflammation is an important causative agent of human morbidity and mortality, such as Systemic Inflammatory Response Syndrome, Multiple Organ Dysfunction Syndrome, and Multiple Organ Failure (1). *Tephrosia Falciformis* Linn is a shrub, found throughout India. Traditionally the plant is digestible, anthelmintic, antipyretic, diseases of liver, spleen, heart, tumours, asthma etc. Leaves are tonic and a promising appetizer, used in piles syphilis and gonorrhoea. (2-4). The phytochemical investigations on *T. falciformis* have revealed the presence of glycosides, rotenoids, flavonoids and sterols (5-8). The literature survey revealed that there are no research studies carried out related to anti-inflammatory and anti-nociceptive activities on the roots of this plant, hence in the present study, ethanol extract of *T. falciformis* root (EETF) were evaluated for anti-inflammatory activities in acute, sub-acute and chronic models as well as anti-nociceptive activity by writhing test and tail-immersion tests were determined.

Materials and Methods

Plant material

The aerial parts of *T. falciformis* (L) was collected from Baripiper, Jodhpur, Rajasthan in September 2005, India and was identified (BIS/DOB.210521) and authenticated by Dr. Jain.SC, Botanist Birla Institute of Research, Jaipur, India. A voucher specimen has been preserved in our laboratory for future reference. The aerial parts were dried under shade, powdered by a mechanical grinder and were passed through 40-mesh sieve and stored in airtight container for further use.
Preparation of Extract

About 1kg of the powdered plant material was exhaustively extracted using ethanol (90%) in a Soxhlet extractor. The ethanolic extracts were concentrated and the traces of the solvent were completely removed under reduced pressure and were stored in vacuum desiccator for further use. The yield of ethanolic extract was found to be (9.6%) w/w with respect to dried powder. The dried extract was suspended in 2% Carboxy Methyl Cellulose (CMC) and used as test drug sample for the animal studies. Similarly, aspirin was suspended in 2% CMC and used as standard drug.

Phytochemical Analysis

The dried extract was subjected to phytochemical analysis for constituent identification using standard protocol (9).

Animals

Wistar Albino rats (150-200g) and Swiss Albino mice (20-35g) of either sex were used in the studies. They were housed in large propylene cages and kept at 22±2°C in 12 h dark-light cycle. The animals were fed with rat pellet food and water ad libitum. All animals were acclimatized for at least one week before the experimental session. All the experimental procedures were done following the guidelines of Institutional Animal Ethics Committee (IAEC).

Drugs and Chemicals

Aspirin, carrageenan, Freund’s adjuvant were purchased from Sigma, Pentazocine was purchased from Ranbaxy Lab Ltd, New Delhi, India. All other chemicals were of analytical grade and procured locally.
Anti-inflammatory activity

Carrageenan induced Paw Edema

Acute inflammation was produced by injecting 1% solution of carrageenan in to plantar surface of rat hind paw at the dose of 0.1ml per 100g body weight (10). Wistar albino rats were divided in to five groups of six in each. A 2% solution of CMC at a dose of 0.1ml/100g/p.o was administered to group 1. The test drug sample was administered to the animals of group 2, 3 and 4 at the dose range of 100, 200 and 400mg/kg/p.o respectively against the standard drug aspirin at 100mg/kg/p.o to the 5. After 30 minutes carrageenan solution was injected to the animals of all the groups. The paw edema was measured at the intervals of 1, 2, 3 and 4h using Plethysmometer (520-R, USA). The paw edema among the different group of animals was compared. Percentages of inhibition were obtained for each group using the following ratio: $\frac{(V_t - V_0)_{control} - (V_t - V_0)_{treated}}{(V_t - V_0)} \times 100$, where $V_t$ is the average volumes for each group and $V_0$ the average volume obtained for each group before any treatment (11)

Cotton pellet induced granuloma

Two autoclaved cotton pellets weighing 10±1mg were implanted in both sides of the groin region of each rat (12, 13). The animals were divided into five groups of six each. The Control group received 2% CMC solution at the dose of 0.1ml/100g/p.o. The test groups were treated with test drug samples for seven consecutive days at the dose of 100, 200 and 400mg/kg/p.o. The standard group received aspirin at the dose of 100mg/kg p.o for seven days. After seven days animals were sacrificed by cervical dislocation and the cotton pellets along with the granuloma tissues were dried in an oven at 60°C, weighed and resulted
weights were compared with the control. The percentage inhibition of granuloma by the test drug was determined.

**Freund’s adjuvant induced arthritis**  
Male albino rats were divided into five groups. On day one 0.1ml of Freund’s adjuvant was injected into the plantar pad of each rat. The control group received 0.1ml/100g/p.o of 2% CMC solution consecutively for 21 days. The three test groups were treated with the test drug samples at the dose of 100, 200 and 400mg/kg/p.o for 21 days. The standard group received aspirin at 100mg/kg/p.o for 21 days (14). The paw edema of each group was measured using Plethysmometer (Model-520-R, USA) on day 1 before and on day 22 after drug administration. The percentage inhibition of arthritis (Paw edema) was calculated.

**Anti-nociceptive activity**

**Tail-immersion test**  
Swiss albino mice of either sex (20-35g) were used in the study. Animals were divided into five groups of six each. Group 1 received 0.1ml of 2%CMC solution as control. The test drug EETF was administered at the dose of 100, 200 and 400mg/kg p.o to the groups 2, 3 and 4 respectively against the standard drug Pentazocine administered to group 5 at the dose of 5mg/kg i.p. The animals were held in a suitable restrainer with tail extending out. The tail up to 5cm was then dipped into a pot of water maintained at 55±0.1°C (15). The time taken for the mouse to withdraw the tail in seconds was considered as the reaction time. The reading was recorded after 30, 60 and 120 min of administration of drugs and control.
**Acetic acid writhing test**

Animals were divided into five groups of six each. The control group received 0.1 ml of 2% CMC solution. The test groups were treated with 100, 200 and 400 mg/kg/p.o. of test drug samples. The standard group received aspirin at the dose of 100mg/kg/p.o. After 30 min of drug administration 0.7% acetic acid was given to each mouse at the dose of 0.1 ml/10g body weight i.p. (16). Number of writhing was counted for 15 minutes. The percentage inhibition of writhing offered by the drug samples to the animals was calculated and compared with the control.

**Statistical analysis**

The values are represented by mean ± SEM; Student’s t-test was performed. P<0.05 was considered as significant.

**Results**

**Phytochemical analysis**

Phytochemical study showed that EETF tested positive for steroid, flavonoids and glycosides.

**Anti-inflammatory activity**

**Carrageenan induced Paw Edema**

The test drug EETF at the dose of 100, 200 and 400 mg/kg p.o showed significant reduction in paw edema (P<0.001) after carrageenan administration. It was observed that EETF at the dose of 400mg/kg/p.o produced 55.14% percentage inhibition of paw edema (Table-1) at the 4th hr of drug administration, whereas, 64.48% was produced by aspirin.

**Cotton pellet induced granuloma**

In granuloma induced sub-acute inflammation model, the test drug EETF at the dose of 200 and 400 mg/kg/p.o. had significant anti-inflammatory activity (P<0.01) (Table-2). The percentage inhibition of granuloma after drug administration was found to be 35.72% for EETF at the dose of 400mg/kg/p.o and 41.88% for the standard drug aspirin.

Freund’s adjuvant induced arthritis

In chronic inflammation induction model, the EETF reduced the arthritis by 11.85% and 16.66% at the doses of 200 and 400mg/kg/p.o. respectively compared to the standard drug aspirin (100 mg/kg/p.o.) which reduced the arthritis by 31.28% (Table-3).

Anti-nociceptive activity

Tail-immersion test
Tail-immersion analgesic method revealed that EETF at all the doses significantly delayed the time of tail withdrawal response by thermal induction of pain at 120 min (P<0.001). EETF at the dose of 400mg/kg/p.o. showed significant protection from nociception at 30, 60 and 120 min similar to the standard drug Pentazocine 5mg/kg i.p. (Table-3).

Discussion

Inflammatory events involve micro-vascular changes with increased vascular permeability, flow of exudation, including plasmatic protein and amplification of endogenous chemical mediators (17). Non Steroidal Anti-Inflammatory Drugs (NSAIDs) are the common drugs against superficial nociception and inflammation. NSAIDs alleviate the hyperalgesic symptoms associated with inflammation by inhibiting the COX enzyme and the resultant inhibition of Prostaglandins synthesis from arachidonic acid (18). In this study a positive step was put forward to investigate the anti-nociceptive and anti-inflammatory actions of *Tephrosia Falciformis* utilized traditionally for nociception and inflammation. The ethanolic extract of the roots of *Tephrosia Falciformis* was found to have significant (P<0.001) anti-inflammatory property in all the dose level in acute carrageenan induced paw edema, a test which has significant predictive value for...
anti-inflammatory agents acting by inhibiting the mediators of acute inflammation (19). In sub-acute and chronic studies, the inflammatory granuloma and arthritis are the typical features (20) which have been reduced significantly (P<0.01) by EETF at the dose level of 200 and 400mg/kg. The percentage protections of inflammation at the dose level of 400mg/kg in acute, sub-acute and chronic model were 55.14 (at 4th hr), 35.72 and 13.91 respectively. It provided the feedback that EETF was more effective in acute than sub-acute and chronic inflammation. The writhing induced by chemical substances is due to sensitization of nociceptors by Prostaglandins. This test is useful for evaluation of mild analgesic non-steroidal anti-inflammatory compounds (21). The ethanolic extract of the roots of *Tephrosia Falciformis* at the dose level of 400mg/kg showed significant (P<0.001) inhibitory activity on the writhing induced by acetic acid when compared to control. Opioid type analgesics can be differentiated from NSAIDs by their effectiveness in the tail-immersion test (22). The tail immersion results depicted that the test drug EETF at the dose level of 100, 200 and 400mg/kg gave significant response (P<0.001) at 120 min. Antinociceptive study by tail-immersion test provided the evidence for central mechanism which is also exhibited by the test drug for relieving the pain. The studies have rationalized the ethno-medicinal utility of the roots of *T. Falciformis* for various ailments related to inflammatory disorders.
